                            //为什么这里i都要乘以3,我猜测
                            这里都是【9】,就是每个传感器都有三组数据,然后用put函数对三组
                            数据选最优,那数据的首地址分别是 0 3 6,注意这里传的是地址
                                                                 //gyro[j]
                        .
是gyro[3];i=0 赋值【0,1,2】 i=1时赋值【3,4,5】.。。
                     //那errcount[i],_priority[i]就应该放的三组数据的比较结果
                     //上面读了i=0时gyro[0,1,2]三组数据 一共读了9组数据
                     这个put函数应该是对这些所取的数据做处理的
                     voter gyro.put(i, sensors.gyro timestamp[i], &gyro[0],
                     sensors.gyro errcount[i], sensors.gyro priority[i]);
                     //执行了3次 这种函数还是实例化分析 现在假设 i=0时
                 /* ignore empty fields */
                 if (sensors.accelerometer timestamp[i] > 0) {
                     _voter_accel.put(i, sensors.accelerometer_timestamp[i],
                     &sensors.accelerometer m s2[i * 3],
                            sensors.accelerometer errcount[i],
                            sensors.accelerometer_priority[i]);
                 }
                 /* ignore empty fields */
                 if (sensors.magnetometer timestamp[i] > 0) {
                     voter mag.put(i, sensors.magnetometer timestamp[i],
                     &sensors.magnetometer ga[i * 3],
                              sensors.magnetometer errcount[i],
                              sensors.magnetometer priority[i]);
          //如果数据的copy不成功,取陀螺仪 加速度
          磁力计的数据,且取三组,i=0,1,2分别是三组数据。将这三组数据传入put函数
          进行最优的选择, errcount[i] priority[i]这里放的应该就是put所做处理的标志
```

```
//那put函数都在做什么 对这三组数据做处理 平均数 方差 标准差 滤波等
//下面的get best函数应该就是根据这些标志 什么方差 标准差,选择最可靠的数据
get best()函数的最后调用该结果(通过比较三组数据的confidence大小决定是否选取)

//构建一个初始的四元数,用四元数来表示姿态时 通过微分方程实时更新解算姿态
但是这种求解也是需要一个初值啊,至于是行是列不重要,这里加速度的测量值作为第三
                                                                      gg: 1751300722
说明这个四元数是由 载体转换到地理,如果是第三列还记得之前的[0 0
1]g得到的第三列吗,这里行不就是转置吗
//i= ( mag - k * ( mag * k))之所以这么复杂 只是在强制使k i叉乘为零,相互垂直。
// k = -
      accel
然后归一化k,k为加速度传感器测量到加速度方向向量,由于第一次测量数据时无人机一般为平稳状态无运
动状态,所以可以直接将测到的加速度视为重力加速度g,以此作为dcm旋转矩阵的第三行k(这个介绍过了
// i= ( mag - k * ( mag * k)) mag向量指向正北方,k*( mag*k)
正交correction值,对于最终的四元数归一化以后的范数可以在正负5%以内;感觉不如《DCM
IMU:Theory》中提出的理论"强制正交化"修正的好,Renormalization算法在ardupilot的上层应用AP AHRS
DCM中使用到了。
// j= k%i : 外积、叉乘。关于上面的Vector<3>k = -_accel, Vector<3>相当于一个类型 (int) 定义一个变量k, 然后把-_accel负值给k, 在定义_accel时也是
使用Vector<3>,属于同一种类型的,主要就是为了考虑其实例化过程(类似函数重载)。

                                                        面根据经纬度获取的磁偏角做
                                                        差值得到纠偏误差角度mag er
                                                          wrap pi函数是用于限定结
                                                        果-pi到pi的函数
   // Project magnetometer correction to body frame
   corr += _q.conjugate_inversed(Vector<3>(0.0f, 0.0f, -mag_err)) * _w_mag;//_w_mag为mag的权重
            // 加速度修正,上面都是用来修正航向的 z轴,但是还有x y靠谁修正,Accelerometer correction
// Project 'k' unit vector of earth frame to body frame
// Vector<3> k = q.conjugate inversed(Vector<3>(0.0f, 0.0f, 1.0f));
// 把归一化的n系重力加速度通过旋转矩阵R左乘旋转到b系 Vector<3> k =
q.conjugate inversed(Vector<3>(0.0f, 0.0f, 1.0f)); R(n->b) 乘以(0,0, 1) q
Vector<3> k(
   2.0f * (_q(1) * _q(3) - _q(0) * _q(2)),

2.0f * (_q(2) * _q(3) + _q(0) * _q(1)),

(_q(0) * _q(0) - _q(1) * _q(1) - _q(2) * _q(2) + _q(3) * _q(3))
);
corr += (k % ( accel - pos acc).normalized()) * w accel;//w开头都是权重
//这就是mahony算法中的的计算过程,只是换了个包装
{k%( accel "加速度计的测量值"-位移加速度)的单位化)<约等于重力加速度g>}*权重。
这里考虑了运动加速度,减去它更可靠,之前都忽略了。(加速度计测量的是
重力加速度+运动加速度)
//总加速度(加速度获取)减去机体运动加速度(第五部分)获取重力加速度,然后姿态矩阵的不是行
就是列来与纯重力加速度来做叉积,算出误差。因为运动加速度是有害的干扰,必须减掉。算法的理论基础是[0,0,1]与姿态矩阵相乘。该差值获取的重力加速度的方向是导航坐标系下的z轴,加上运动加速度之后,总加速度的方向就不是与导航坐标系的天或地平行了,所以要消除这个误差,即"_accel-_pos
acc"。
-
7/然后叉乘z轴向量得到误差,进行校准
                                 Retten 99: 1751300722
// 陀螺仪误差估计 Gyro bias estimation
_gyro_bias += w gyro bias * corr *
这里类似与KI的效果
for (int i = 0; i < 3; i++) {
   _gyro_bias(i) = math::constrain(_gyro_bias(i), - bias max, bias max);
rates = gyro + gyro bias;//角速度 = 陀螺仪的测量值 + 误差校准
// 前馈 Feed forward gyro
corr += rates;
//最后就是使用修正的数据更新四元数,并把 rates和 gyro bias置零便于下次调用时使用。
// 对状态进行修正,实际上 就是关键的姿态更新 Apply correction to state
q += q.derivative(corr) * dt;
   非常重要,又用到了微分方程离散化的思想。以前讲过DCM矩阵更新过程中也是用到了该思想。
   //
```

}

```
先看看代码,有点怪,怪就怪在derivative(衍生物)这个名字上,平时一大推的论文和期刊上面
       都是用的omga *Q 的形式,而这里的代码实现确是用的Q *
       omga的形式,所以构造的4*4矩阵的每一列的符号就不一样了。
       //http://blog.csdn.net/qq_21842557/article/details/51058206最后
    q.normalize();
